1 Strategy

2 EMF chain

3 BESSER chain

4 Validation

5 Limitations

A Rule-to-reference traceability

B Full results

C Metamodels

D Test instances

E Reproducing the results

1 Strategy

Terms are those of the EMF chain's glossary, `emf/GLOSSARY.md`.[1]

Missing: The strategy, independent of either chain. Waits on the team.

- The problem: exams into a fixed number of batches so that no student sits two exams of the same batch; an exam's weight is its student count.
- The two formulations, the paper's (Σ $\S$3.3, Eqs. (3)–(10)) (each exam in exactly one batch, penalties only), which BESSER implements, and the weighted one (each exam in at most one batch, weights as priorities; `emf/docs/adr/0030`), which EMF implements. On four mutually conflicting exams in three batches (BESSER's `none`, EMF's `clique`) their objectives: one conflict accepted, or Validation left with no valid assignment.
- Why simulated annealing as well: the paper samples by quantum annealing on D-Wave hardware; the chains use its classical counterpart, as the notebook (Σ cell 15) does (quantum annealing itself is issue #22).

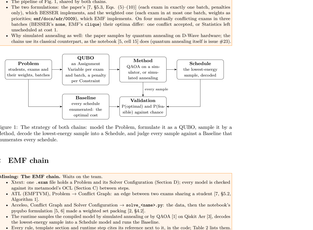

Figure 1: The strategy of both chains: model the Problem, formulate it as a QUBO, sample it by a Method, decode the lowest-energy sample into a Schedule, and judge every sample against a Baseline that enumerates every schedule.

2 EMF chain

Missing: The EMF chain. Waits on the team.

- Xtext: one `.exam` file holds a Problem and its Solver Configuration (Section D); every model is checked against its metamodel's OCL (Section C) before anything else.
- ATL (EMFTVM), Problem → Conflict Graph: an edge between every two exams sharing a student (Σ $\S$3.2, Eq. (2)).
- Acceleo, Conflict Graph and Solver Configuration → `solve.cmake`: per the chain, then the notebook's pyqubo formulation (Σ, 6) made a weighted set packing (Σ $\S$4.2).
- The runtime samples the compiled model by simulated annealing or by QAOA (Σ) on Qiskit Aer [3], decodes the lowest-energy sample into a Schedule model and runs the Baseline.
- Every rule, template action and runtime step cites its reference next to it, in the code; Table 2 lists them.

3 BESSER chain

Missing: The BESSER chain. Waits on the BESSER rework.

T1 (Problem → QUBO, rule B1; T2 (QUBO → Schedule, rule B2); T3 (Schedule → Validation, rule B3); the BESSER's `qiskitconnector` and the mapping of variables to batches, with the reference of each rule. BESSER's code cites the paper as `[Zhou]`, with `[Paper, ...]` tags. Section A could list its rules too.

4 Validation

Missing: How the chains are validated. Waits on the team.

What every run measures: the Schedule found, whether it is feasible and optimal against the Baseline, P(optimal) and P(feasible) over every shot or read, and the odds of a uniformly random bit string, the bar a Method must clear. The EMF chain also checks its formulation in every run: a sample's energy is minus the weight it places; exactly when it breaks no Constraint. Each chain is measured on its own instances (Section D); every run is by Section B.

Missing: These EMF numbers come from a local run, not from CI. Waits on CI.

Once CI has uploaded an `emf-results` artifact (push #24 and #25), `scripts/build_ab.sh` or `build_ab --run <id>` for a pull request's run.

Table 1: P(optimal) of the EMF chain on each test instance (Section D) by Method, against a uniformly random bit string's; it includes how many times chance. Settings in Table 3; from a local run.

Instance	Variables	Random	QAOA	Simulated annealing
path	8	0.0078	0.188 (14×)	0.940 (120×)
cycle	15	0.0002	0.033 (36×)	1.000 (1092×)
clique	12	0.0015	0.042 (28×)	0.940 (642×)
semester	18	0.000046	0.00024 (5×)	0.960 (20972×)

Missing: The BESSER chain's table, P(optimal) against chance on its instances. Waits on the BESSER rework.

From `besser/output/instances/N_validation.json` once the chain settles.

5 Limitations

Missing: The limitations. Waits on the team.

- QAOA is far behind simulated annealing (Table 1), and only simulated, on at most 18 qubits.
- The QAOA runtime starts from a fixed ramp of angles, which follows the annealing path only when γ and β have opposite signs; flipping the mixer's sign raised P(optimal) everywhere and P(optimal) in 8 of 9 cases (`emf/docs/adr/0031`); the remaining 1 of 9 is open.
- The simulated annealing is classical: no quantum annealer was used (issue #22).
- The Baseline enumerates every schedule, so validation stops at about 10^6 schedules.
- The Schedule the generated script writes is not validated against its metamodel's OCL.
- The BESSER chain's own.

A Rule-to-reference traceability

Table 2: Every ATL rule, template section and runtime step of the EMF chain that implements the formulation or QAOA, with the reference its comment cites, read from the code.

Unit	What it implements, as its comment says
ATL problem2conflictgraph.atl	Problem → Conflict Graph
rule Problem2ConflictGraph	Σ, §3.2, Eq. 2: the conflict graph G, exams as nodes and conflicts as edges.
rule Problem2ConflictGraph	Σ, §3.3, Eq. (4): at least one M-valuation, so the M-valuation bound the schedule.
rule ExamExam	Σ, §3.2, Eq. 2: each exam is a node of G.
rule ExamExam	Σ, §3.2, Eq. 2: of the set packing objective, the exam's priority
rule NoSwitch	Σ, §3.3, Eq. (4): batch k is column k of X, $k = 1..M$.
rule AtMostOneSwitch	Σ, §3.3, Appendix A, Eq. (10): $C[q] = 1$ if some student sits both exam i and exam j.
lazy rule Conflict	Σ, §3.2, Eq. 2: one edge of G per pair with $C[q] = 1$, emitted once, in problem order.
Acceleo, main.mtl: Conflict Graph and Solver Configuration → `solve.cmake`: **py**	
CONFLICTS	Σ, §4.2, hyperlink 5, Eq. (3) Σ, cell 7: C, the contradictive matrix, as pairs (i, j).
x	Σ, §3.3, Eq. (4), cell 11: $x_{ik} = 1$ iff exam i is in batch $k = 1$.
constraint1	Σ, §4, knows penalties, cell 11: x_{ik} [6]; each exam in at most one batch, the paper's exactly-one (Σ, §3.3, Eqs. (5)–(7)) relaxed (ADR-0009). With one batch there is no pair to forbid.
constraint2	Σ, §3.3, Eq. (8), cell 11: $x_{ik} x_{jk}$ [6]; conflicting exams never share a batch, the paper's $x_{ik} x_{jk} = 0$. Σ, §4.2, knows penalties, cell 11.
profit	Σ, §4.2 Σ, §4.2, Eq. (3) Σ: scheduling exam i earns its weight; an unscheduled exam earns 0.
0, 8, model	Σ, §3.3, Eq. (10) Σ, cell 10: H_c with lambda = gamma = A and the profit omitted. A is fed from the Solver Configuration
Python, ensemble.py: the runtime the generated scripts call	
schedule_of	Σ, §3.3: the batch where x_{ik} rounds over all X, x[i, k] = 1 iff exam i is in batch k = 1.
penalty	A: the largest weight plus one unless set. An explicit A must exceed every weight, or breaking a constraint can cost less than leaving an exam unscheduled (ADR-0009). [4, §4.2]: "Choosing $B < A$ ensures that it is never favorable to violate a constraint to improve the objective." [5, §3.2]: "Choose the Scalar Penalty P." If large enough, a hard constraint is never broken.
anneal	Σ, cell 15]: simulated annealing (neal) on the BQM, then pyqubo decodes every read.
qaoa	Σ, Eqs. (1)–(6): QAOA on the bling form of the compiled model, simulated on Qiskit Aer [3], with the ramp of angles and the shots the runtime's inputs fix.
qaoa	[4, §2.3, Eq. (12)]: pyqubo's spins, $s = (1 - 1/2)$, $s \mapsto 1 - 2x$.
qaoa	Σ, Eq. (51): $|e\rangle$, the uniform superposition, top eigenstate of the mixer B.
qaoa	Σ, Eq. (5): alternating problem and mixer layers.
qaoa	Σ, Eq. (2): cost layer $U(C, \gamma)|s\rangle = \exp(-i \gamma \cos\pi C)|s\rangle = \pm|s\rangle$. [4, §1, §2.1, Eq. (2)]: $H_c|x\rangle = \pm|x\rangle$, ± 1 and ± 0 on each $|x\rangle$, $x \in \{0, 1\}^n$.
qaoa	Σ, Eq. (6): $U(B, \beta)|s\rangle = \prod_i \exp(-i \beta X_i)|s\rangle$, X_i on qubit i.
expected_energy	Σ, Eq. (7): $\hat{p}$, the expectation of the cost in the state; estimated from the shots.
qaoa	Σ, Eq. (8): the classical loop optimizes the $2p$ angles.

Missing: The BESSER chain's rules and their references. Waits on the BESSER rework.

Once its code cites [key: locator] as the EMF chain's does, `generate.py` can read it too.

B Full results

Missing: These EMF numbers come from a local run, not from CI. Waits on CI.

Once CI has uploaded an `emf-results` artifact (push #24 and #25), `scripts/build_ab.sh` or `build_ab --run <id>` for a pull request's run.

Table 3: Every run of the EMF chain: each test instance solved by both Methods, with the constructed seeds; the Penalty Coefficient A used; the Schedule's cost and Unscheduled Exams; the Baseline's optimal cost, and P(optimal) and P(feasible) against a uniformly random bit string's. From a local run.

Instance	Var.	Method	A	Result	Optimal cost	P(optimal) cost	P(feasible) random	cost
path	8	QAOA, depth 3, COBYLA, 150 shots	4	0, none	0	0.106	0.0078	0.535	0.180
path	8	simulated annealing, 50 reads × 10000 sweeps	4	0, none	0	0.940	0.0078	1.000	0.180
cycle	15	QAOA, depth 3, COBYLA, 150 shots	2	0, none	0	0.033	0.00002	0.200	0.012
cycle	15	simulated annealing, 50 reads × 10000 sweeps	2	0, none	0	1.000	0.00002	1.000	0.012
clique	12	annealing, 50 reads × 10000 sweeps	3	1, Statistics	1	0.940	0.0015	1.000	0.018
clique	12	annealing, 50 reads × 10000 sweeps	3	1, Statistics	1	0.042	0.0015	0.531	0.018
semester	18	annealing, 50 reads × 10000 sweeps	4	0, none	0	0.960	0.000046	1.000	0.0024
semester	18	QAOA, depth 3, COBYLA, 150 iterations, 4096 shots	4	0, none	0	0.00024	0.000046	0.587	0.0024

Missing: The BESSER chain's runs. Waits on the BESSER rework.

From `besser/output/instances/N_validation.json` once the chain settles.

Table 4: The EMF chain with other QAOA settings, every one reaching the optimal cost. Measured on macOS before **`emf/requirements.txt`** was pinned, so a rerun may differ in the second digit; copied by hand from **`emf/GUIDE.md`**. COBYLA stops well before 150 iterations (27 to 71 evaluations); a Powell iteration is a line search over single-QUBO evaluations on cycle15.

Instance	Variables	Method	P(optimal)	P(feasible)
path	8	QAOA, depth 1, COBYLA, 150 iterations, 2048 shots	0.051	0.305
path	8	QAOA, depth 2, COBYLA, 150 iterations, 2048 shots	0.088	0.590
path	8	QAOA, depth 3, Powell, 150 iterations, 2048 shots	0.075	0.804
cycle	15	QAOA, depth 1, COBYLA, 150 iterations, 4096 shots	0.0007	0.006
cycle	15	QAOA, depth 2, COBYLA, 150 iterations, 4096 shots	0.0007	0.006
cycle	15	QAOA, depth 3, Powell, 150 iterations, 4096 shots	0.132	0.512

Missing: The BESSER chain's full results. Waits on the BESSER rework.

Every instance's metrics, from `besser/output/summary.md` or its JSONs.

C Metamodels

Containment is drawn with a diamond at the container, a reference with an open arrow; for names an OCL invariant.

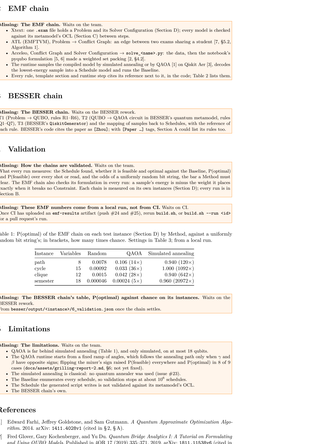

Figure 2: The problem metamodel, drawn from `problem.ecore`.

Figure 3: The subversonally metamodel, drawn from `solversonlgf.ecore`.

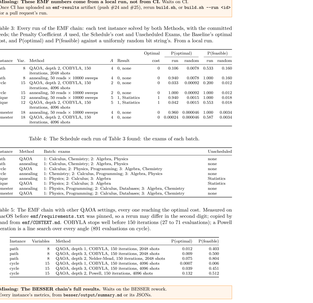

Figure 4: The conflictgraph metamodel, drawn from `conflictgraph.ecore`.

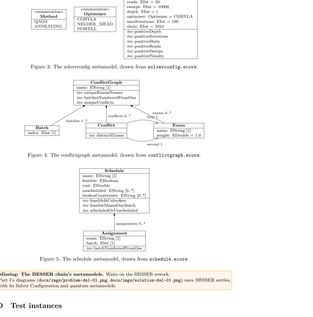

Figure 5: The schedule metamodel, drawn from `schedule.ecore`.

Missing: The BESSER chain's metamodels. Waits on the BESSER rework.

Part I's diagrams (`docs/imgs/problem-dsl-01.png`, `docs/imgs/solution-dsl-01.png`) once BESSER settles, with its Solver Configuration and quantum metamodels.

D Test instances

The EMF chain's instances, **`emf/instances/`**. Each has a twin, `N.qubo` (`<name>-qaoa.exam` or `<n>-<name>-annealing.exam`), holding the same problem already solved by the other Method.

```
3-path.exam
// Q4: four exams whose conflicts form a path, two batches. Feasible (a path is 2-colorable).
problem path batches 2
students Ana Bob Eva
exam Algebra    weight 2 { Ana }
exam Biology    weight 3 { Ana Bob }
exam Physics    weight 1 { Bob Eva }
exam Chemistry  weight 2 { Eva }

solver { method QAOA depth 3 optimizer COBYLA iterations 150 shots 2048 seed 7 }
```

```
3-cycle.exam
// Q4 (5.1): three exams whose conflicts form a 3-cycle, three batches. Feasible (needs 3 batches).
// Two batches are provably not enough (= no schedule where no many exams as it can.
problem cycle batches 3
students Ana Bob Eva Lin Lia
exam Algebra    { Ana Bob }
exam Calculus { Ana Eva }
exam Physics { Bob Eva }
exam Chemistry { Eva Lin }
exam Programming { Ana Lia }

solver { method QAOA depth 3 optimizer COBYLA iterations 150 shots 4096 seed 7 }
```

```
5-clique.exam
// Q4 (5.1): four-exam mess that all conflict, three batches. No schedule places them all: the
// largest-weight exam, Statistics, is left unscheduled, at cost 1 (ADR-0009).
problem clique batches 3
students Ana Bob Eva
exam Algebra    weight 4 { Ana Bob }
exam Calculus   weight 3 { Ana Eva }
exam Physics    weight 2 { Bob Eva }
exam Statistics weight 1 { Ana Bob Eva }

solver { method annealing reads 50 sweeps 10000 seed 7 }
```

```
6-semester.exam
// Q4 (5.2): six exams of a semester, three batches. Feasible.
problem semester batches 3
students Ana Bob Eva Lin Lia Tom
exam Algebra    weight 5 { Ana Bob }
exam Calculus   weight 4 { Ana Eva Tom }
exam Physics    weight 3 { Bob Eva }
exam Chemistry  weight 2 { Lin Lia }
exam Programming weight 1 { Lia Tom }
exam Databases  weight 1 { Tom Ana }

solver { method annealing reads 50 sweeps 10000 seed 7 }
```

Missing: The BESSER chain's instances. Waits on the BESSER rework.

`besser/instances/`: tiny, many, none, medium and limit.

E Reproducing the results

- The EMF chain: **`cd emf && ./build.sh`** (JDK 21+, Python 3.12) builds the chain and runs it on every instance, writing **`emf/out/<name>/results_<name>.json`**. The Python packages, pyqubo [4], Qiskit and Qiskit Aer [3], and dimod among them, are pinned in **`emf/requirements.txt`**. CI runs the same on every push (`.github/workflows/emf.yml`) and uploads the results as the **`emf-results`** artifact.
- This report: **`docs/report_2/build.sh`** (TeX Live, gs) fetches those results from CI, generates its tables, Section A and the diagrams of Section C, and runs latexmk; it does not run the chains.
- The LEM top of Part II: **`docs/lia_usage_2.sed`**, with the session records it links in **`docs/assets/`** and **`besser/docs/lia_usage_2.sed`**.

Missing: How to reproduce the BESSER chain's results. Waits on the BESSER rework.

`besser/README.md`'s commands, once the chain settles.

[1] BESSER's metamodels, from Part I, call a Batch a *TimeSlot* (or *slot*) and a feasible Schedule *valid*.
